# Scheduling Analysis with Monte Carlo Simulation and Statistic Method on a Building Construction Project 

Syadza Nabila Yusna*, Agus Suharyanto, Indradi Wijatmiko

University of Brawijaya, Malang, Indonesia

#### Abstract

. In the construction of an office building in Indonesia, a delay occurred in the first-floor concrete work. The project was planned to be completed in 161 days but it took 168 days to complete. This study analyzed the issues that arose by doing a scheduling analysis and by comparing the Monte Carlo Simulation and the Statistic method. A comparison between these methods was carried out to determine the project duration scheduling probability level from each method. The data included in the study were the project's Time Schedule and the interview data from respondents who were directly related to the office building construction project. Monte Carlo Simulation analysis showed that to get a $100 \%$ probability level, the duration can only be accelerated by two days, from 168 days to 166 days, while the Statistical method analysis showed that to get a 99.99\% probability level the duration can only be accelerated by 4,2 days, from 168 days to 163.8 days. From the results above, it can be concluded that the Monte Carlo Simulation has a more accurate calculation than the Statistic Method because the result from the Monte Carlo Simulation was 166 days with a $100 \%$ probability level. It is close to the project realization duration which was 168 days.

Keywords: construction delay analysis, monte carlo simulation, statistic method comparison

## 1. Introduction

In construction projects, scheduling is the key that holds the success of a project. The scheduling of a construction project should be planned carefully and optimally to avoid delays in project time. The deadline is in every general project, which means that the project must be completed before or on time. But in reality, a project duration doesn't always match the schedule that has been made. In construction projects, there are several types of scheduling methods that are commonly used for both small and large-scale projects.

Previous studies indicate that if a project is delayed, it can be rescheduled. Bustamin M. O., [1] research whose analysis uses the Monte Carlo Simulation shows that the shortest acceleration duration is 90 days with a $5 \%$ probability level, and the longest
acceleration duration is 99 days with a $100 \%$ probability level. Pratama Y. A. [2] research whose analysis uses the PERT and Z Distribution Statistic Method shows that the shortest acceleration duration is 163 days which is faster than the planning (191 days) and realization (231 days). However, schedule completion with 163 days duration only gave a $57,1 \%$ probability level.

Based on the previous studies above, the Project Evaluation and Review Technique (PERT), Monte Carlo Simulation, and Z Distribution Statistic Method can be used to reschedule a project. Analysis of the project's scheduling method with the application of the PERT, Monte Carlo Simulation, and Z Distribution Statistic Method will be implemented in the construction of an office building in Indonesia, a delay occurred in the first-floor concrete work, and the project was planned to be completed in 161 days but in reality, it took 168 days to complete [3].

Both of Monte Carlo Simulation and Statistic Method analysis will provide a duration probability level. These methods will then be compared to see which method is the most accurate. The results of the comparative analysis from these methods are expected to help project workers to be able to plan project schedules with a high duration probability level [4].

## 2. Methods

The object of this study is an office building project in Indonesia that was delayed for seven days. This research was conducted by analyzing several methods, namely the Project Evaluation and Review Technique (PERT), Monte Carlo Simulation, and Z Distribution Statistic Method. The PERT method required the project's Time Schedule and interview data from respondents who are directly related to the office building construction project such as the Project Manager, Site Engineer, Engineer, etc. who had a minimum of five years of working experience. Obtained data then will be analyzed using these steps: 1) calculating the duration of each activity based on the results of the $\mathrm{a}, \mathrm{m}$, and b duration, 2) rescheduling each activity using the TE duration, 3) identifying the duration and determining the relationship between activities, 4) building a network diagram, 5) calculating the ES, EF, LS, LF, and TF value.

After the calculation of the PERT Method is done, the next step is to analyze it with Monte Carlo Simulation and Statistic Method. Monte Carlo Simulation is analyzed by determining the number of literation that is needed for the simulation. Z Distribution Statistic Method will be analyzed by determining each activity's standard deviation and variance and then analyze the probability level. Both of these methods will provide
a duration probability level, a comparison is made to see which method is the most accurate.

## 3. Result and Discussion

### 3.1. Project evaluation and review technique

Data for calculations in this study were obtained from interviews, data obtained from the respondents are optimistic duration (a), most likely duration (m), and pessimistic duration (b). Respondents who were interviewed are people that are directly related to the office building construction project such as Project Manager, Site Engineer, Engineer, etc. who had a minimum of five years of working experience. The results from the interviews were then averaged based on the $a, m$, and $b$, for each activity [5].

### 3.1.1. Expected duration analysis

After determining the estimated numbers for $a, m$, and $b$, the next step is to analyze the relationship between the three numbers into one expected duration number (TE). For example, the calculation for activity A would look as follow:

$$
\begin{equation*}
\frac{17+(4 \times 19)+22}{6}=19 \tag{1}
\end{equation*}
$$

Calculations for the expected duration (TE) can be seen in Table 1.
After obtaining the TE duration, a network diagram needed to be made to get the total duration of the building construction work in this study.

### 3.1.2. Building a network diagram

Large-scale projects require careful planning, scheduling, and coordinating various interrelated activities for the project to be successful. Therefore, a procedure was developed based on the use of a network diagram. The type of activity, the relationship between activities, and the duration of each activity are used as a reference in making the network. An example of a network diagram can be seen in Figure 1.

Figure 1: Network diagram.

### 3.1.3. Earliest start, earliest finish, latest start, and latest finish

After the network diagram has been made, the calculation for ES, EF, LS, and LF can be done. Earliest start (ES) is the fastest time an activity can be started, earliest finish (EF) is the fastest time an activity can be finished, latest start (LS) is the slowest time an activity can be started, and latest finish (LF) is the slowest time an activity can be finished. The calculation of ES, EF, LS, and LF can be seen in Table 2.

After the ES, LS, and EF, LF values are obtained, the Total Float can be calculated.

### 3.1.4. Total float

Calculation of the total float is implemented on all activities. From the ES, EF, LS, and LF values, the total float can be analyzed. Total float can be analyzed using this formula.

$$
\begin{equation*}
T F=L F-- \text { Duration }--E S \tag{2}
\end{equation*}
$$

Calculations of the Total Float can be seen in Table 3.
From the Total Float Calculation, it can be seen that there are some TF with 0 values. This shows that the critical path is in the activities with 0 values TF.

### 3.1.5. Critical path

The critical path can be seen from activities that have TF with 0 values. Based on the calculations above, the activities that are on the critical path are:

Table 2: ES, EF, LS, and LF.

| N | 29 | 59 | 93 |
| O | 29 | 59 | 100 |
| P | 28 | 88 | 121 |

1. Activity A: Preparation work.
2. Activity C: Earth and sand work.
3. Activity E: Concrete Work (1st floor).
4. Activity F: Masonry and Plaster (1st floor).
5. Activity U: Roof Work.
6. Activity AD: Lightning Rod Work

The critical path formed from these activities is A-C-E-F-U-AD. The critical path needs to be determined because only activities that are on the critical path have an influence on the acceleration of the total project's duration.

### 3.2. Monte carlo simulation

The first step in Monte Carlo Simulation is to determine iteration value is by calculating the standard deviation. The maximum and minimum values are 168 and 154 days, and the total population is two. Standard deviation is calculated by using this formula [6].

$$
\begin{equation*}
\sigma=\sqrt{ } \frac{\sum(168-154)^{2}}{2}=9,89 \tag{3}
\end{equation*}
$$

The second step is to determine the absolute error value which is less than $1 \%$, absolute error is calculated by using this formula:

$$
\begin{equation*}
=\frac{154}{\frac{1}{0,01}}=1,54 \tag{4}
\end{equation*}
$$

The last step is to determine the number of iterations required with less than $2 \%$ error, number of iterations is calculated by using this formula:

$$
\begin{equation*}
N=\left(\frac{3 \times 9,89}{1,54}\right)^{2}=371,90=372 \tag{5}
\end{equation*}
$$

From the calculations above, the number of iterations for the Monte Carlo Simulation is 372 times.

### 3.2.1. Monte carlo simulation calculation

In this study, Monte Carlo simulation is analyzed by generating a random number using the RAND function in Microsoft Excel. For example, the calculation for activity A would look as follows:

$$
\begin{equation*}
=\operatorname{RAND}() *(22-17)+17 \tag{6}
\end{equation*}
$$

Monte Carlo simulation calculation is only implemented on activities whose activities are in a critical path. The calculation for the Monte Carlo simulation can be seen in Table 4.

TABLE 4: Monte carlo calculation.

| Activity | Duration <br> (a) | Iteration <br> (b) | Iteration <br> 1 | Iteration <br> 2 | Iteration <br> 3 | Iteration <br> 4 | Iteration <br> 5 | Iteration <br> 6 | Duration7 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |
| A | 17 | 22 | 19 | 19 | 20 | 22 | 20 | 18 | 20 |
| C | 17 | 21 | 19 | 19 | 20 | 19 | 18 | 20 | 20 |
| E | 36 | 48 | 47 | 43 | 48 | 46 | 42 | 38 | 39 |
| F | 27 | 31 | 28 | 29 | 30 | 29 | 28 | 29 | 31 |

|  |  | Total | 158 | 154 | 162 | 165 | 150 | 151 | 149 |
|  | (a) | (b) | 366 | 367 | 368 | 369 | 370 | 371 | 372 |
| A | 17 | 22 | 17 | 20 | 19 | 18 | 22 | 17 | 17 |
| C | 17 | 21 | 17 | 18 | 18 | 20 | 20 | 18 | 17 |
| E | 36 | 48 | 37 | 38 | 45 | 41 | 45 | 40 | 46 |
| F | 27 | 31 | 28 | 29 | 28 | 29 | 29 | 30 | 27 |
| U | 37 | 43 | 39 | 42 | 41 | 42 | 39 | 42 | 38 |
| AD | 3 | 6 | 5 | 5 | 4 | 4 | 4 | 3 | 4 |
|  |  | Total | 145 | 151 | 156 | 153 | 157 | 150 | 150 |

The calculation results from the table above are then translated into a graph to see the percentage of the probability level duration.

### 3.2.2. Monte carlo simulation duration probability level graph

Based on Table 4, a frequency distribution and graph combination of Probability Density Function (PDF) and Cumulative Distribution Function (CDF) can be made. PDF is a function that gives a likelihood of a random variable to have a value, CDF is a function that sums the possible values up to a certain event. Table of analysis of simulation results with PDF and CDF values can be seen in Table 5.

The graph of the duration probability level $1 \%$ error value, with a combination of PDF and CDF can be seen in Figure 2.

From the table and the graph, it can be seen that the shortest duration is 143 days, but the duration probability level is only $0,27 \%$ with a risk of failure $99,73 \%$. To get a $100 \%$ probability level with $0 \%$ risk of failure, the required duration is 166 days.

Table 5: Monte carlo calculation with PDF and CDF.

| Activity | Duration |  | Iteration | Iteration | Iteration | Iteration | Iteration | Iteration | Iteration |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| AD | 3 | 6 | 5 | 5 | 4 | 4 | 4 | 3 | 4 |
|  |  | Total | 145 | 151 | 156 | 153 | 157 | 150 | 150 |

Figure 2: Monte carlo duration probability level.

### 3.3. Z distribution statistic method

Estimation for the PERT method uses a time span and not a definite period of time. This time span marks the degree of uncertainty. The parameters that describe this problem are known as Standard Deviation and Variance. The smaller the value of the Variance indicates more certain activity can be completed and vice versa.

Standard Deviation and Variance can be calculated using the following formulas:

$$
\begin{equation*}
S=\frac{1}{6} x b-a \tag{7}
\end{equation*}
$$

$$
\begin{equation*}
V=S^{2} \tag{8}
\end{equation*}
$$

Calculations for Standard Deviations and Variances can be seen in Table 6. From the calculation above, V values that on the critical path is 6,35.

### 3.3.1. Analysis of scheduling target

According to the network diagram that has been made, the total expected duration (TE) $=154$ days, and the total activity variance $\left(\mathrm{V} / \mathrm{S}^{2}\right)=6,35$. The relationship between the expected time (TE) and the target (TD) is stated in $z$. The probability level of the project being completed on the desired target (TD) = 161 days can be determined by using the following calculation:

$$
\begin{equation*}
z=\frac{T(d)-T E}{\sqrt{ } S}=\frac{161-154}{\sqrt{ } 6,35}=\frac{7}{2,52}=2,78 \tag{9}
\end{equation*}
$$

$z=2,78=0,9973$ (obtained from Z Cumulative Normal Distribution Table)
Probability value = 0,9973 $\times 100 \%=99,73 \%$
To obtain several possibilities from the project duration, several calculations were taken. The results of the sample can be seen in Table 7.

According to the Table, it can be seen that the shortest duration is 145 days, but the duration probability level is only 0,02\%. To get a 99,99\% probability level, the required duration is 163,8 days.

### 3.4. Comparative analysis between monte carlo simulation and Z distribution statistic method

Monte Carlo Simulation is analyzed by generating a random number using the RAND function in Microsoft Excel. From the calculation, the number of iterations that needed is 372 times. Based from the iterations, the duration obtained varies from the shortest duration which is 143 days, and the longest duration which is 166 days. From the table and graph, it can be seen that the shortest duration (143 days) probability level is $0,27 \%$, while the Iongest duration (166 days) probability level is 100\%. Z Distribution Statistic Method is analyzed by determining Standard Deviation and Variance from estimated numbers of optimistic duration (a), most likely duration (m), and pessimistic duration (b) [7]. From the calculations it can be seen that the duration obtained varies from the

TABLE 6: Standard deviations and variances.

| 160 | 2,38 | 0,9913 | $99,13 \%$ |
| 161 | 2,78 | 0,9973 | $99,73 \%$ |
| 162 | 3,17 | 0,9992 | $99,92 \%$ |
| 163 | 3,57 | 0,9998 | $99,98 \%$ |
| 163,8 | 3,89 | 0,9999 | $99,99 \%$ |

probability level for the shortest ( 145 days) is $0,02 \%$ and the duration probability level for the longest duration (163,8 days) is 99,99\%.

## 4. Conclusion

Based on the discussion and analysis that has been described previously, several conclusions are obtained:

1. Monte Carlo Simulation analysis shows that the shortest duration of 143 days only has a $0,27 \%$ probability level, whereas the 166 days duration has an $100 \%$ probability level, which is only two days different from the realization duration (168 days).
2. Analysis using the Statistic Method shows that the shortest duration of 145 days but with a probability level of only 0,02\%. To get a 99,99\% duration probability level, the building construction work must be done in 163,8 days, which 4,2 days different from the realization duration (168 days)
3. Analysis using the Monte Carlo Simulation has a more accurate calculation than using the Statistic Method because the Monte Carlo Simulation analysis obtained result is 166 days with an 100\% probability level, close to the project realization duration which is 168 days. While the Statistic Method obtained a duration which is 163,8 days with a probability level $99,99 \%$, which 4,2 days different from the realization duration (168 days).
